Abstract

We present the main features of the explicitly covariant Light-Front Dynamics formalism and a summary of our recent works on this topic. They concern the bound states of two scalar particles in the Wick-Cutkosky model and of two fermions interacting via the usual OBEP ladder kernels.

1 Motivation

The recent measurements performed at CEBAF/TJNAF on the deuteron structure functions and tensor polarization up to momentum transfer values yet never reached, was the starting motivation for a series of works in relativistic dynamics. Indeed the measurement of the electromagnetic form factors at values $Q^2 \approx 6 \text{ (GeV/c)}^2$, much greater than the nucleon mass, lets no hope for any attempt to describe this physics without relativity. There are even very few chances that meson-nucleon dynamics could still be used while the distances involved are smaller than the nucleon itself $R_N \approx 0.86 \text{ fm}$. A recent and complete reviews of both the experimental and theoretical works can be found in [1, 2] and references therein.

This motivation has always been present in theoretical physics since the first days of quantum mechanics. It relies on the need for having a proper relativistic wavefunction of simple systems – an essential ingredient in the NN , $q\bar{q}$, qqq , ... physics – and for clarifying the kind of modifications that Lorentz invariance brings into the non relativistic dynamics.

Our first contribution in this field consisted in a series of papers [3, 4, 5, 6] which, in the framework of the Explicitly Covariant Light-Front Dynamics (ECLFD), led us to predict the deuteron structure functions and polarization observables. These calculations, though performed in a perturbative way over the wavefunctions of the Bonn model [7], turned to be quite successful in the deuteron case and have recently found a natural application in describing the NN correlation functions in nuclei (see Prof. Antonov contribution to this School and [8]). The success encountered in these first works and some clear advantages of the ECLFD itself in describing relativistic composite systems, convinced us to go deeper inside this approach both in developing formal aspects of the theory and in studying in detail the properties of its solutions. This effort has up to now resulted in studying the bound states solutions of two scalar and two fermions systems in the ladder approximation. Doing so, we have in mind the description of "genuine relativistic systems" (those for which $B \sim m$, $\beta \sim 1$) as well as the *a priori* non relativistic ones when probed in relativistic regions (e.g. deuteron).

¹Now at Geneva University and CERN, Switzerland

In this contribution, we first present the leading ideas of the ECLFD formalism (Section 2) and then summarize the main results of our recent works [9]-[18] on this topic, both in the scalar (Section 3) and fermionic (Section 4) case. We put special emphasis in the following items: i) the size and nature of relativistic effects ii) the comparison with the non relativistic solutions and other relativistic approaches iii) the problem of constructing the non zero angular momentum states and iv) the solution of the OBEP models for fermions and their stability properties with respect the cutoff.

2 The formalism

Light-Front Dynamics is an hamiltonian formulation of the quantum field theory, specially well adapted to the description of relativistic composite systems. In its explicitly covariant version, proposed by V.A. Karmanov [19] and recently reviewed in [5, 20], the state vector is defined on a space-time hyperplane whose equation is given by $\omega \cdot x = \sigma$ with $\omega^2 = 0$. Wavefunctions - defined as the Fock components of the state vector - are the usual formal objects of this theory and are directly comparable to their non relativistic counterparts.

As in any hamiltonian formalism, the dynamical equations are provided by the eigenvalue equations of the two Casimir operators of the Poincaré group, respectively the square of the four-momentum $\hat{P}^\mu$ and of the Pauli-Lubanski $\hat{S}_\mu$ four-vectors

$$\hat{P}^2 | \Psi > = M^2 | \Psi > \quad (1)$$

$$\hat{S}^2 | \Psi > = -M^2 J(J+1) | \Psi > \quad (2)$$

These operators are quadratic forms of the ten generators $\{\hat{P}_\mu, \hat{J}_{\rho\sigma}\}$ of the Poincaré group:

$$\begin{aligned} \hat{P}^2 &= \hat{P}_\mu \hat{P}^\mu \\ \hat{S}_\mu &= \frac{1}{2} \epsilon_{\mu\nu\rho\sigma} \hat{P}^\nu \hat{J}^{\rho\sigma} \end{aligned}$$

Different ways of constructing the generators set would lead to different relativistic theories [21] which will be furthermore strictly equivalent if they were solved in their full complexity. This choice is provided by integrating the Noether conserved currents over a suitable 3D space-time surface. We remind that Noether theorem associates to each continuous space-time transformation

$$x \rightarrow x' = \Lambda x + a \quad (3)$$

letting invariant a lagrangian density

$$\mathcal{L}(x) = \mathcal{L}_0(x) + \mathcal{L}_{int}(x) \quad (4)$$

a 4-current j^μ satisfying the continuity equation

$$\partial_\mu j^\mu = 0 \quad (5)$$

This latter is calculated from a particular $\mathcal{L}(x)$ according to very precise recipes. Integrating over an arbitrary 4D volume V (figure 1), equation (5) is equivalent to assert the nullity of flux across its boundary ∂V

$$\int_{\partial V} j^\mu dS_\mu = 0 \quad (6)$$

Figure 1: Arbitrary volume V for integrating continuity equation

where dS^μ denotes the normal to ∂V .

Equation (6) leads to a conservation law only if V is such that "lateral flux" vanishes. In the usual approach of dynamics – denoted "instant-form" in Dirac classification [21] – V is the space-time volume limited by the hyperplane $t=\text{cte}$ (see figure 2). In Light-Front Dynamics – denoted "front-form" in [21] – V is limited by two space-time planes $\omega \cdot x = \sigma$ (see figure 3).

Figure 2: Flux in instant-form of dynamics

Figure 3: Flux in front-form of dynamics

Let us illustrate the procedure in case transformation (3) is a translation

$$x_\nu \rightarrow x'_\nu = x_\nu + a_\nu$$

Noether theorem provides a set of four 4-currents $\{T^{\mu\nu}\}_{\nu=0,3}$ given by

$$T^{\mu\nu} = \frac{\partial \mathcal{L}}{\partial(\partial_\mu \phi)} \partial^\nu \phi - g^{\mu\nu} \mathcal{L}$$

and satisfying

$$\partial_\mu T^{\mu\nu}(x) = 0$$

They constitute the energy-momentum tensor. Integrating the continuity equation over an arbitrary space-time V one gets

$$\int_V d^4x \partial_\mu T^{\mu\nu} = 0$$

and choosing V like in figure 2 gives

$$\left[\int d\vec{x} T^{0\nu}(x) \right]_{upper} + \left[\int d\vec{x} T^{0\nu}(x) \right]_{lower} = 0$$

That means the four quantities

$$\hat{P}^\nu(t_0) = \int d\vec{x} T^{0\nu}(x)$$

are independent of the hyperplane $t = t_0$ position.

Alternatively, by choosing space-time planes $\omega \cdot x = \sigma$, one obtains the ω -dependent generators

$$\boxed{\hat{P}^\mu(\sigma) = \int T^{\mu\nu}(x) \delta(\omega \cdot x - \sigma) \omega_\nu d^4x} \quad (7)$$

with

$$\partial_\sigma \hat{P}^\mu(\sigma) = 0$$

Equation (7) is the starting point of the Light-Front Dynamics.

In the instant-form approach, the spatial components depend only on the non interacting part of the lagrangian and are called kinematical. The zero-th component is the interaction Hamiltonian and governs the dynamics

$$\begin{aligned} P^0 &= H_{int} \\ \vec{P} &= \vec{P}_0 \end{aligned}$$

In LFD, all generators split into a free part ($\hat{P}_0^\mu$) and an interaction-dependent one ($\hat{P}_{int}^\mu$)

$$\boxed{\hat{P}^\mu(\sigma) = \hat{P}_0^\mu + \hat{P}_{int}^\mu(\sigma)}$$

with the interaction dependent part being along the ω -direction

$$\boxed{\hat{P}_{int}^\mu(\sigma) = \omega^\mu \int H_{int}(x) \delta(\omega \cdot x - \sigma) d^4x}$$

This can be turn to profit to obtain a maximum number of seven non interacting generators, an advantage that was already noticed by Dirac in his seminal paper [21] about the different forms of relativistic dynamics.

Once obtained the generators, (1) provides the dynamical equation determining the mass of the system M^2 . After some algebra, one is led to

$$\boxed{(M^2 - P_0^2) | \Psi \rangle = 2P_0 \cdot \omega \int \mathcal{H}_{int}(\omega\tau) \exp(-i\sigma\tau) d\tau | \Psi \rangle} \quad (8)$$

where $\mathcal{H}_{int}(k)$ denotes the Fourier transform of the hamiltonian density

$$\mathcal{H}_{int}(k) = \int \mathcal{H}_{int}(x) \exp(ik \cdot x) d^4x$$

We will consider hereafter the σ -stationary solutions and set $\sigma = 0$ in (8). The evolution of states towards σ is given in [18].

The state vector is decomposed into its Fock components $\Psi_{\alpha\beta}$ ²

$$|\Psi\rangle = \sum_{\alpha\beta} \int d^4k_1 \dots d^4k_\alpha d^4q_1 \dots d^4q_\beta \Psi_{\alpha\beta}(k_1, \dots, k_\alpha, q_1 \dots q_\beta) a_{k_1}^\dagger \dots a_{k_\alpha}^\dagger b_{q_1}^\dagger \dots b_{q_\beta}^\dagger |0\rangle \quad (9)$$

which are the wavefunctions. We can consider the set $\Psi_{n_{\alpha\beta}} \equiv \{\Psi_{\alpha\beta}\}$ as the components of an infinite dimensional vector $\Psi = (\Psi_1, \Psi_2, \Psi_3, \dots)$, coupled to each other via the interaction operator $\int \mathcal{H}_{int}(\omega\tau) d\tau$. Equation (8) is thus an infinite system of coupled channels.

$$(M^2 - P_0^2) \begin{pmatrix} \dots \\ \Psi_2 \\ \Psi_3 \\ \dots \end{pmatrix} = 2P_0 \cdot \omega \int \mathcal{H}_{int}(\omega\tau) d\tau \begin{pmatrix} \dots \\ \Psi_2 \\ \Psi_3 \\ \dots \end{pmatrix}$$

If we restrict ourselves to the two- ($\Psi_2 \equiv \{\Psi_{20}\}$) and three-body ($\Psi_3 \equiv \{\Psi_{21}\}$) wavefunctions, we obtain a system of two coupled equations for Ψ_2 and Ψ_3 which constitutes the ladder approximation. By expressing Ψ_3 in terms of Ψ_2 , one gets an integral equation for Ψ_2 with energy dependent kernel.

The construction of non zero angular momentum states in LFD is made difficult by the fact that generators of spatial rotations contain the interaction. Consequently the eigenvalue equation for $\hat{S}^2$ and $\hat{S}_3$ are non trivial dynamical equations with a level of complexity higher than the mass equation (8) one. To circumvent this difficulty we have made use of a kinematical angular momentum operator

$$\vec{J} = -i \left(\vec{k} \times \frac{\partial}{\partial \vec{k}} + \hat{n} \times \frac{\partial}{\partial \hat{n}} \right)$$

whose eigenstates can be constructed by using the standard angular momentum algebra. The physical solutions are then obtained as a linear combination of the kinematical operator $\hat{A}^2 \equiv (\vec{J} \cdot \hat{n})^2$ eigenstates, satisfying the so called "angular condition". This method was shown to restore – at least in a simple model – the rotational invariance of the theory to a high degree of accuracy [17]. Its explanation requires long technical developments and will not be detailed here. The interested reader could find the first published results in [10, 12, 17].

An important property of Light-Front Dynamics is the fact that the vacuum of the theory is decoupled from any other Fock state despite the interaction. This "emptiness of the vacuum" results into the absence of vacuum fluctuations diagrams and considerably simplifies the evaluation of certain processes.

²We consider two interacting fields with corresponding creation operators $a_k^\dagger$ and $b_q^\dagger$

An appreciable advantage of this formalism with respect to other relativistic approaches, is the clear link with the usual non relativistic dynamics: LFD wavefunctions have the same physical meaning of probability amplitudes than their non relativistic counterparts.

Among the drawbacks we note – apart from the psychological barrier of using a non conventional formalism – the appearance of contact (instantaneous) interactions for non scalar constituents and two direct consequences of solving the dynamical equations in a truncated Fock space: the ω dependence of the on-shell approximate amplitudes and the fact that the different projections of the non-zero angular momentum states along the $\vec{\omega}$ direction are non degenerate (the so called violation of the rotational invariance).

It could be of some help to say few words about the words in what concerns the Light-Front world. Historically it appeared first in Dirac classification with the particular choice of front surface $t - z = 0$. It reappeared in Quantum Field Theory in 1966, under the label "Infinite Momentum Frame" calculations, when it was realized [23] that boosting the frame in which calculations of invariant amplitudes are made, gave easier results. In particular all diagrams related to vacuum fluctuations automatically vanished. Later on, it was shown [24] that this procedure was equivalent to use the LFD variables $z \pm t$ in the theory from the very beginning and constitutes now the so called standard LFD, developed by many authors [25, 26, 27, 28, 29, 30, 31, 32, 33, 34].

The difference with respect to our approach is in the words "Explicitly" and "Covariant" which we will try to justify. To choose a front surface in the form $\omega \cdot x = \sigma$ is not only a mathematical "delicatesse" but a way to carry everywhere in the theory the ω -dependence of the formal objects in an explicit way. It has several advantages, all related to the fact that ω is a four vector with well defined transformation properties. For instance it provides explicitly covariant expressions for the on shell amplitudes, a property which is often hidden in the standard LFD formulation. The latter one is recovered by fixing the value $\omega = (1, 0, 0, -1)$ but this value is associated to a particular reference frame and it is not valid in any other one, what implies a non covariant formulation. Another advantage of the covariant formulation is the fact that, because the ω -dependence is explicit, it can be controlled at will and removed when calculating observables (e.g. in the form factors [35]).

If by covariance of a theory, we understand the fact that is based on a set of generators satisfying the Poincaré algebra, then the standard and the explicitly covariant approaches would be both covariant if they were solved in their full complexity. This is never the case in practice, in particular due to the Fock space truncation, and both formulations can lose this property when approximate schemes are used.

3 Two Scalar particles

It is always instructive to start by considering a simple model which could provide us with some physical insight with a lower formal cost. We have thus considered the Wick-Cutkosky (WC) model [36] describing two scalar particles (m) interacting by a scalar exchange (μ) with a Lagrangian density $\mathcal{L}_I = g\varphi^2\chi$. We are interested in bound states of two particles with momenta k_1 and k_2 . In the reference frame $\vec{k}_1 + \vec{k}_2 = 0$ the ECLFD equation reads

$$[4(k^2 + m^2) - M^2]\Psi(\vec{k}, \hat{n}) = -\frac{m^2}{2\pi^3} \int \frac{d^3k'}{\epsilon_{k'}} V(\vec{k}, \vec{k}', \hat{n}, M^2) \Psi(\vec{k}', \hat{n}) \quad (10)$$

where $\vec{k}=\vec{k}_1$, $\epsilon_k = \sqrt{k^2 + m^2}$, $\omega = (1, \hat{n})$ in this particular frame with $\hat{n}^2 = 1$ – and M the total mass of the system, related to its binding energy B by $M = 2m - B$.

The interaction kernel is³

$$V(\vec{k}, \vec{k}', \hat{n}, M^2) = -\frac{4\pi\alpha}{Q^2 + \mu^2}$$

with

$$Q^2 = (\vec{k} - \vec{k}')^2 - (\hat{n} \cdot \vec{k})(\hat{n} \cdot \vec{k}') \frac{(\epsilon_{k'} - \epsilon_k)^2}{\epsilon_{k'} \epsilon_k} + \left(\epsilon_k^2 + \epsilon_{k'}^2 - \frac{M^2}{2} \right) \left| \frac{\hat{n} \cdot \vec{k}'}{\epsilon_{k'}} - \frac{\hat{n} \cdot \vec{k}}{\epsilon_k} \right| \quad (11)$$

Relativistic effects are all included in the second and third $\hat{n}$ -dependent terms of Q^2 . By formally setting $\hat{n} = 0$ in this expression – though $\hat{n}^2 = 1$! – one recovers the non relativistic Coulomb kernel. By furthermore assuming $B \ll m$, the kinematical left hand side term of (10) becomes $4m(k^2 + B)$ and the ECLFD equation coincides with the non relativistic Schrodinger equation in momentum space for Coulomb interaction⁴.

Equation (10) was solved [9, 18] for several values of J and μ . For S- waves, the solution Ψ is a scalar function depending on two scalar arguments $\Psi = \Psi(k, \hat{n} \cdot \vec{k})$, i.e. the LFD S-wave wavefunction has an angular dependence! For non-zero angular momentum states the solution was obtained on a basis of eigenfunctions of the $\hat{A}^2$ operator, discussed in the previous section. In a truncated Fock space, these eigenfunctions were found to have different M^2 values [10, 12] – a result also noticed in [37] – and a method was proposed to restore in the two-body sector the rotational invariance. Our main results concerning S-waves are summarized in what follows. The numerical values given hereafter all correspond to $\hbar = c = m = 1$ units.

Size and nature of relativistic effects

The size and nature of relativistic effects in the binding energies can be seen in figure 4. The LFD results for $\mu = 0$ are compared to the non relativistic ones and to those given by the Klein-Gordon equation. One can see a quick departure from Schrodinger results and a clear repulsive character - smaller binding energy - contrary to Klein-Gordon (and Dirac) equations which produces attractive corrections to all orders. LFD energies are also compared to a first order perturbative calculations – equally valid for Bethe-Salpeter (BS) equation – which have the form [38]

$$B_{pert} = \frac{m\alpha^2}{4} \left(1 - \frac{4}{\pi} \alpha \log \frac{1}{\alpha} \right) \quad (12)$$

and turn to be relevant until $\alpha \approx 0.3$.

It is worth noticing that sizeable relativistic effects are observed in a system for which both the binding energy and the average momentum are small. At $\alpha = 0.3$, for instance, they account for a 100% effect in the binding energy whereas $\frac{\langle k^2 \rangle}{m^2} \approx 2\%$.

We would also like to notice that the large differences between the ECLFD and the non relativistic solutions are not of kinematical origin. In order to disentangle the different contributions to the relativistic energies B , equation (10) has been formally written $K\Psi = \frac{1}{\epsilon} V\Psi$

³Strictly speaking, the Wick-Cutkosky model corresponds to the $\mu = 0$ case. We consider here a trivial extension

⁴We note a missprint in page 465 of [11] where the expression $4mk^2 + 2mB$ was instead written

Figure 4: LFD energies (solid) for $\mu = 0$ as a function of α , compared with non relativistic, Klein-Gordon and perturbative results

Figure 5: Contribution of different relativistic corrections (see text for details)

and we have considered several approximations of it. The results are displayed in figure 5. We have first considered the case of a non relativistic kernel V – i.e. put $\hat{n} = 0$ in (11) and $\epsilon = m$ – together with in curve a the non relativistic kinematics $K = 4m(k^2 + B)$ and in curve a' the relativistic one $K = 4(k^2 + m^2) - M^2$. Curves b and b' are obtained in the same manner but putting $\epsilon = \sqrt{k^2 + m^2}$. The last one corresponds to the full ECLFD equation. These results show that – at least in what scalars are concerned – the main effect of a relativistic formalism is not in the kinetic energy but in the interaction kernel. The kinematical term K has a very little influence on B , which furthermore goes on the opposite direction, whereas ϵ and V kernel contribution are both essential. One can thus conclude that kinematical corrections alone are not representative of relativistic effects. Even when they are included in the kernel, e.g. through ϵ_k , they can only account for half the effect.

Comparison with Bethe-Salpeter equation

The comparison with Bethe-Salpeter equation is done in figures 6 and 7. Figure 6 represents the LFD $B(\alpha)$ curves (solid line) for different values of μ . They are compared with those provided by BS equation (dashed-line) in the same ladder approximation, whose kernel incorporates higher order intermediate states. Their results are seen to be close to each other. This fact is far from being obvious – specially for large values of coupling constant – due to the differences in their ladder kernel. A quantitative estimation of their spread can be given by looking into an horizontal cut of figure 6, i.e. calculating the relative difference in the coupling constant $(\alpha_{LFD} - \alpha_{BS})/\alpha_{LFD}$ for a fixed value of the binding energy. The results, displayed in figure 7 for $B = 1.0, 0.1, 0.01$, show that relative differences (i) are decreasing functions of μ for all values of B (ii) increase with B but are limited to 10% for the strong binding case $B = m$ which involves values of $\alpha \geq 5$. This indicates the relatively weak importance of including higher Fock components in the ladder kernel even for strong couplings, as was noticed in [31].

Figure 6: $B(\alpha)$ for different values of μ in LFD (solid) and BS (dashed) approaches

Figure 7: Differences in the coupling constant as a function of μ for fixed values B .

Weak binding limit and non relativistic solutions

An interesting result was obtained by studying the weak binding limit of $B(\alpha)$. We found that, except for the case of zero mass exchange, relativistic and non relativistic solutions differ even when describing zero binding energy systems. These results are displayed in figures 8 and 9. BS solutions, also included, display the same behaviour, indicating that this is not a pathology of the Light-Front formalism but seems rather a general feature of consistent relativistic theories. A system bound by a massive exchange would be described by different parameters whether one uses LFD (and BS) or Schrodinger approaches, no matter how small the binding energy will be. We concluded from that to the non existence of non relativistic limit for $\mu \neq 0$.

We would like to mention here that an important part of these differences were taken into account by including in the Schrodinger equation energy dependent interactions [40].

The scalar deuteron

A straightforward application to this model, and a way to evaluate the modifications induced by a relativistic treatment of a semi-realistic model, was done by building a scalar model for deuteron. By adding a "repulsive scalar" term⁵ one gets a relativistic version of the Nucleon-Nucleon MT potential [39].

$$V = V_R + V_A = \frac{\lambda_R}{Q^2 + \mu_R^2} - \frac{\lambda_A}{Q^2 + \mu_A^2} \quad (13)$$

In the non relativistic limit, $\lambda_R, \mu_R, \lambda_A, \mu_A$ are adjusted to reproduce a realistic deuteron wave-function with $B = 2.23$ MeV and acceptable NN scattering parameters. If one inserts kernel (13)

⁵One should note that such a repulsive interaction cannot arise from a scalar exchange but can mimic some fermionic interactions

Figure 8: Zero binding energy limit of LFD and BS equations (solid) compared with non relativistic solutions (dot-dashed) for $\mu = 1$

Figure 9: The same study for different values of μ . LFD and BS curves are not distinguished

in the LFD equations, the binding energy is shifted from $B = 2.23$ to $B = 0.96$ MeV, a dramatic repulsive effect. One can recover the physical value for B by shifting $\lambda_R = 7.29 \rightarrow \lambda_R = 6.60$ – all other parameters being unchanged – what makes a 10% difference in a coupling constant. The spectacular change in B is partially due to the small value of the deuteron binding energy. It illustrates however well the difficulty to unambiguously determine a coupling constant in the strong interaction physics, even for systems widely considered as being *a priori* non relativistic.

Wavefunctions

The main modification when comparing LFD and NR wavefunctions with the same coupling constant is due to the change in the corresponding binding energies. A first requirement to compare them is thus to re-adjust one of the α values (we choose the NR one) in order to deal with states of equal B . Figure 10 shows the comparison of these wavefunctions, squared and integrated over the angular dependence $\hat{n} \cdot \hat{k} \equiv \cos \theta$, for $\mu = 0$ and a moderate coupling $\alpha = 0.5$. One then has $B_{LFD}=0.0267$ and $B_{NR}=0.0625$ which has been re-scaled to the LFD value with $\alpha = 0.327$. One can see small deviations ($\approx 5\%$) at $k = 0$. In the relativistic region, the LFD solutions are systematically smaller than the NR ones and their differences increase reaching a factor 3 for $k = 2$, despite the moderate values of B and α . When dealing with highly relativistic systems – like e.g. mesons in the constituent quark model – both descriptions differ even for small values of k . Figure 11 shows the case $B_{LFD}=0.84$ and $\alpha = 5$ where the squared wavefunctions at $k = 0$ are $\approx 70\%$ different.

Figure 10: LFD and Schrodinger wavefunctions, squared and integrated over θ for $\mu = 0$.

Figure 11: Similar comparison in a highly relativistic case ($\alpha = 5$)

4 Two fermions system

We have also obtained [13, 14, 18] recently the LFD bound state solutions for a system of two fermions interacting with the usual – scalar (S), pseudoscalar (PS), pseudovector (PV) and vector (V) – OBEP Lagrangians:

$$\begin{aligned}
 \mathcal{L}_s &= g_s \bar{\Psi} \phi \Psi \\
 \mathcal{L}_{ps} &= g_{ps} \bar{\Psi} i \gamma_5 \phi \Psi \\
 \mathcal{L}_{pv} &= \frac{g_{pv}}{2m} \bar{\Psi} \gamma_5 \gamma_\mu \partial^\mu \phi \Psi \\
 \mathcal{L}_v &= \bar{\Psi} [g_v \gamma^\mu A_\mu + \frac{f_v}{2m} \sigma^{\mu\nu} (\partial_\mu A_\nu - \partial_\nu A_\mu)] \Psi
 \end{aligned}$$

As in the scalar case, calculations were performed in the ladder approximation. The interaction kernel is provided by the Born scattering amplitude $\mathcal{M}$ and – according to the Light-Front graph technique – has two contributions which differ from each other by the light-front time ordering. Its analytical structure has the form

$$\mathcal{M} = \{A_1(k'_1, k_1, \tau') + A_2(k_1, k'_1, \tau)\} [u_{\sigma'_1}(k'_1) \hat{O}_1 \bar{u}_{\sigma_1}(k_1)] [u_{\sigma'_2}(k'_2) \hat{O}_2 \bar{u}_{\sigma_2}(k_2)]$$

where $\hat{O}_i$ are vertex operators depending on the type of coupling ($\hat{O}_i = \mathbf{1}, i\gamma_5, \dots$) and A_1, A_2 scalar functions. In "center of mass" variables, i.e. boosting to a reference frame in which $\vec{k}_1 + \vec{k}_2 = 0$, the scalar part can be written as

$$A_1(\vec{k}, \vec{k}', \hat{n}, M) + A_2(\vec{k}, \vec{k}', \hat{n}, M) = \frac{1}{Q^2 + \mu^2}$$

with Q^2 given by (11) and the total amplitude reads

$$\mathcal{M}_{\sigma'_1 \sigma'_2, \sigma_1 \sigma_2} = \frac{1}{Q^2 + \mu^2} [u_{\sigma'_1}(k'_1) \hat{O}_1 \bar{u}_{\sigma_1}(k_1)] [u_{\sigma'_2}(k'_2) \hat{O}_2 \bar{u}_{\sigma_2}(k_2)]$$

$$\mathcal{M} =$$

$k'1 + \omega\tau'' = k1 + q + \omega\tau'$
 $k'1 + q = k1 + \omega\tau + \omega\tau''$

As in the scalar case, the two-fermion LFD wavefunctions Φ are Fock components of state vector (9). Their spin structures depend on the quantum numbers of the state. For $J^\pi = 0^+$ they have the form

$$\Phi_{s_1 s_2}(k_1, k_2, p, \omega) = \bar{u}_{s_2}(k_2) \hat{\phi} \gamma_5 U_C \bar{u}_{s_1}(k_1) \quad (14)$$

with

$$\hat{\phi} = \phi_1 + \left[\frac{2m\gamma_\mu \omega^\mu}{\omega \cdot p} - \frac{4m^2}{s} \right] \phi_2$$

depending on two scalar functions ϕ_i . For $J^\pi = 1^+$ they read

$$\Phi_{s_1 s_2}^\lambda(k_1, k_2, p, \omega) = \epsilon_\mu^\lambda(p) \bar{u}_{s_2}(k_2) \hat{\phi}^\mu U_C \bar{u}_{s_1}(k_1) \quad (15)$$

in which

$$\begin{aligned} \hat{\phi}_\mu &= \phi_1 \frac{(k_1 - k_2)_\mu}{2m^2} + \phi_2 \frac{\gamma_\mu}{m} + \phi_3 \frac{\omega_\mu}{\omega \cdot p} + \phi_4 \frac{(k_1 - k_2)_\mu \hat{\omega}}{2m(\omega \cdot p)} \\ &+ \phi_5 \frac{i\gamma_5 \epsilon_{\mu\nu\rho\sigma} (k_1 + k_2)_\nu (k_1 - k_2)_\rho \omega_\sigma}{2m^2 \omega \cdot p} + \phi_6 \frac{m\omega_\mu \hat{\omega}}{(\omega \cdot p)^2} \end{aligned}$$

p is the total momentum, $U_C = \gamma_2 \gamma_0$ the charge conjugation operator, $e_\mu^\lambda(p)$ the polarization vector and $\hat{\omega} = \gamma_\mu \omega^\mu$. They depend on six scalar functions ϕ_i .

To get easier links with the non relativistic wavefunctions one uses instead of ϕ_i some linear combinations denoted f_i . For 0^+ states, for instance, one simply has

$$\begin{aligned} f_1 &= 2\sqrt{2}\epsilon_k \phi_1 \\ f_2 &= 2\sqrt{2}k_{\epsilon_k} \phi_2 \end{aligned}$$

with f_1 tending to the usual NR wavefunction and f_2 being an extra component of relativistic origin with no counterpart. For 1^+ states the combination is more involved [3] but the f_i functions have similar properties. Thus f_1 tends to the non relativistic S-wave component u_S , f_2 tends to the D-waves $-u_D$ and f_{3-6} are extra components of relativistic origin.

One can see that in this f -representation, LFD provides a very interesting parametrization of the relativistic dynamics. One deals with similar formal objects, depending on similar

arguments. In this way, relativity acts by modifying the usual wavefunctions and by introducing extra components which becomes negligible – or tends to zero – in the non relativistic regime.

In Φ representation (14-15) the two-body LFD equation reads

$$\begin{aligned} \left[M^2 - (k_1 + k_2)^2 \right] \Phi_{\sigma_1 \sigma_2}^\lambda(k_1, k_2, p, \omega \tau) &= \frac{m^2}{2\pi^3} \sum_{\sigma'_1 \sigma'_2} \int \frac{d^3 k'_1}{2\epsilon_{k'_1}} \frac{d^3 k'_2}{2\epsilon_{k'_2}} d\tau' \delta(k'_1 + k'_2 - p - \omega \tau) \quad (16) \\ 2(\omega \cdot p) \times \Phi_{\sigma'_1 \sigma'_2}^\lambda(k'_1, k'_2, p, \omega \tau') &\times V_{\sigma'_1 \sigma'_2, \sigma_1 \sigma_2}(k'_1, k'_2, p, \omega \tau'; k_1, k_2, p, \omega \tau) \end{aligned}$$

Inserting (14-15) in (16) one is left – after some lengthy algebra – with a set of coupled two-dimensional integral equations on the form

$$A_\alpha(k) \phi_\alpha(k, u) = \sum_\beta \int dk' du' B_{\alpha\beta}(k, u, k', u') \phi_\beta(k', u') \quad (17)$$

where $u = \hat{n} \cdot \hat{k}$. A_α contains kinematical terms and $B_{\alpha\beta}$ the interaction kernel. For $J^\pi = 0^+$ there are two coupled equations whereas for $J^\pi = 1^+$ their number is six but can actually be decoupled into 2+4 [18].

B_{ij} results from integration over φ' , the azimuthal angle between $\hat{k}$ and $\hat{k}'$, of more basic kernels κ_{ij}

$$B_{ij}(k, u, k', u') = \frac{1}{\pi^2} \frac{k'^2}{\epsilon_{k'}} \int_0^{2\pi} \kappa_{ij}(k, u, k', u', \varphi') \frac{F^2(Q^2)}{Q^2 + \mu^2} \frac{d\varphi'}{2\pi}$$

which have the general structure

$$\kappa_{ij}(k, u, k', u', \varphi') = \frac{1}{4} \sum_{\alpha\beta} L_{\alpha\beta} \text{Tr} \{ \mathbf{M}_{ij}^{\beta\alpha} \}$$

F is a vertex form factor (FF) depending on Q^2 , $L_{\alpha\beta}$ is a tensor depending on the kind of coupling, $\mathbf{M}_{ij}^{\beta\alpha}$ is a contraction of a product of "γ-like" matrices with a tensor $\Pi_{\mu\nu}$ depending on the J^π of the state.

$$\mathbf{M}_{ij}^{\beta\alpha} = \sum_{\mu\nu} \Pi_{\mu\nu} S_i^\mu (\hat{k}_2 + m) O_2^\beta (\hat{k}'_2 + m) S_j^{\nu'} (\hat{k}'_1 - m) \bar{O}_1^\alpha (\hat{k}_1 - m)$$

where $\hat{k} = \gamma_\mu k^\mu$ and $S_i^\mu, S_i^{\mu'}$ are some spin operators [14, 18].

Kernels κ_{ij} are in general calculated numerically. Only for some special cases it is interesting to deal with analytical expressions, which very soon turned out to be unreasonably lengthy. As an example we give below the scalar kernel for $J=0^+$ states:

$$\begin{aligned} \kappa_{11} &= -\alpha_s \pi \left\{ (\varepsilon_k^2 + \varepsilon_{k'}^2)(m^2 - kk' \sin \theta \sin \theta' \cos \varphi') + 2\varepsilon_k \varepsilon_{k'} (\varepsilon_k \varepsilon_{k'} - kk' \cos \theta \cos \theta') \right\} \\ \kappa_{12} &= -\alpha_s \pi m \left\{ (\varepsilon_k^2 - \varepsilon_{k'}^2)(k' \sin \theta' + k \sin \theta \cos \varphi') \right\} \\ \kappa_{21} &= -\alpha_s \pi m \left\{ (\varepsilon_{k'}^2 - \varepsilon_k^2)(k \sin \theta + k' \sin \theta' \cos \varphi') \right\} \\ \kappa_{22} &= -\alpha_s \pi \left\{ (\varepsilon_k^2 + \varepsilon_{k'}^2)(m^2 \cos \varphi' - kk' \sin \theta \sin \theta') + 2\varepsilon_k \varepsilon_{k'} (\varepsilon_k \varepsilon_{k'} - kk' \cos \theta \cos \theta') \right\} \end{aligned}$$

where we denote $\alpha_s = \frac{g_s^2}{4\pi}$. Other analytical expressions have also been obtained and can be found in [13, 14, 15, 18].

4.1 Results

In a series of works [9]-[18] still in progress we have separately studied, coupling by coupling, $J^\pi = 0^\pm, 1^\pm$ states in the loosely bound ($B \ll m$) and ultra relativistic ($B \sim m$) limits. We will restrict ourselves in this contribution to scalar (S) and pseudoscalar (PS) couplings with special emphasis in the stability problem – are equations soluble as they are provided by Quantum Field Theory or do they rather need some regularization? – and in their comparison with the non relativistic solutions.

Figure 12: Cutoff dependence of M^2 in the $J = 0^+$ state, for two fixed coupling constant below and above the critical value.

Figure 13: Cutoff dependence of the coupling constant, for $J = 1^+$ states and $B = 0.05$.

4.1.1 The stability problem

Let us solve the LFD equations in a compact domain $[0, k_{\max}]$

$$\left[M^2 - 4(k^2 + m^2) \right] f(k, u) = \int_0^{k_{\max}} dk' \int_{-1}^{+1} du' B(k, u, k', u') f(k', u')$$

and ask ourselves what happens with M^2 when $k_{\max} \rightarrow \infty$. In case the solution exists, we will say that equations are stable. In the opposite case, the theory would require some regularization procedure, for instance by means of vertex form factors, and it is then pertinent to inquire how the solutions depend on them. We have shown that the answer to this question critically depends on the type of coupling, on the J^π quantum numbers of the state and on the value of the coupling constant α .

Consider first the scalar coupling (Yukawa model) for $J=0^+$. We found [14] the existence of a critical coupling constant $\alpha_c \approx 3.72$, below which the solution exists, and above which the system "collapses". This behavior is illustrated in figure 12 where we have plotted the M

dependence on k_{max} for two different values of α . We showed the asymptotical behavior of solutions to be

$$f(k, u) = \frac{g(u)}{k^{2+\beta}}$$

with a relation $\beta(\alpha)$ provided by an eigenvalue equation that allows a precise determination of the critical value $\beta(\alpha_c) = 0$. This property was checked by a direct inspection of the numerical

Figure 14: Asymptotics of f_i for $J = 0^+$ state with $B=0.05$, $\alpha=1.096$, $\mu=0.25$. The power-law coefficients are $\beta_1 = 0.82$ and $\beta_2 \approx 0$

Figure 15: Asymptotics of f_i for $J = 0^+$ state with $B = 0.5$, $\alpha=2.48$, $\mu=0.25$. The power-law coefficients are $\beta_1 = 0.55$ and $\beta_2 \approx 0$

solutions of LFD equations – as it can be seen in figures 14 and 15 – and turns to be very accurate. It is worth noticing that – at least in the framework of this model – the coupling constant could be ”measured” in the tail of the wavefunction! The $J=1^+$ states, on the contrary, do not present any stable solution without vertex form factors. This can be seen in figure 13 where the divergency of the coupling constant as a function of k_{max} is displayed for the two angular momentum projections of a $J=1^+$ state with $B = 0.05$. One can also remark in this figure the non degeneracy of the different projections due to the Fock space truncation; for the scalar coupling and moderate values of $k_{max} \sim 10$, it remains however less than one percent.

For pseudoscalar coupling, the stability analysis was performed using the same methods than for the scalar one [16, 18] and presents some peculiarities. Quite surprisingly, the equations for $J=0^+$ states were found to be stable without any regularization. The results were however strange in the sense that they lead to a quasidegeneracy of the coupling constants for binding energies which can vary over all the physical range $[0, 2m]$. One gets for instance $\alpha = 49.5$ for $B = 0.001$ whereas $\alpha = 48.6$ for a binding energy 500 times bigger $B = 0.5$. The origin of this anomaly was found to lie in the second channel equation (κ_{22}). It has been understood analytically [16] with a simple model but leads to physically unacceptable results.

The case of other couplings (PV,V,T) has been examined in [18]. Corresponding equations results into more singular kernels which all lead to unstable solutions without form factors.

4.1.2 Comparison with non relativistic solutions

We will present the results for $J = 0^+$ states – so with a two-component wavefunction – obtained with the scalar and pseudoscalar coupling. In each of them, we will consider a loosely bound ($B=0.001$) and a very relativistic ($B=0.5$) system. We have fixed for all the calculations an exchanged mass $\mu = 0.15$.

Figure 16: LFD and non relativistic wavefunctions for $J=0^+$ state with $B = 0.001$, $\mu = 0.15$ in the Yukawa model

Figure 17: Comparison between LFD (Yukawa model), WC and NR $B(\alpha)$ in $J = 0^+$ state

Scalar coupling

For $B = 0.001$, the LFD coupling constant is $\alpha_{LFD}=0.331$ whereas the non relativistic value is $\alpha_{NR}=0.323$. Like in the Wick-Cutkosky model discussed in the last section – scalar particles interacting by scalar exchange – relativistic effects are repulsive. They are responsible for only a 3% difference in the coupling constants, whereas in the purely scalar case this difference is sensibly greater ($\alpha_{WC}=0.364$). Wavefunctions – suitably re-scaled – are displayed in figure 16. One sees that component f_1 dominates over f_2 in all the interesting momentum range and that f_2 has a zero at $k \approx 0.25$. One can also remark that f_1 is very close to the NR wavefunction in the small momentum region but it sensibly deviates with increasing k ; for $k \sim 1.5$ the difference represents more than one order of magnitude in the probability densities. The coupling between the two LFD amplitudes has a very small (0.1%) and attractive effect in the binding energy.

In the strong binding limit ($B=0.5$) the situation is quite similar with enhanced relativistic effects. One has $\alpha_{LFD}=2.44$ for $\alpha_{NR}=1.71$ and the differences in the wavefunctions – displayed in figures 18 and 19 – are already visible at $k = 0$ (figure 18). One can see however in figure 19 that – even for deeply bound systems – f_1 component still dominates over f_2 . To complete these results, we have displayed in figure 17 the LFD, NR and WC coupling constants for different

values of the binding energy. One can see that the LFD results are systematically closer to the non relativistic values than α_{WC} are, as if the fermionic character of the constituents generates closer binding energies to the NR case, but larger differences in the high momentum components of the wavefunction, due to the different asymptotics of interaction kernels.

Figure 18: LFD and non relativistic wavefunctions for $J=0^+$ state with $B = 0.5$, $\mu = 0.15$ in Yukawa model

Figure 19: LFD and non relativistic wavefunctions for $J=0^+$ state with $B = 0.5$, $\mu = 0.15$ in Yukawa model

Pseudoscalar coupling

For pseudoscalar coupling the situation is more involved. First the use of vertex form factor – though not necessary for getting convergent solutions – is essential to ensure physically meaningful results. We have chosen, as in [7], a form factor

$$F(Q^2) = \left(\frac{\Lambda^2 - \mu^2}{\Lambda^2 + Q^2} \right)^n$$

with $\Lambda = 1.3$ and $n = 1$.

In the weak binding limit ($B=0.001$) one has $\alpha_{LFD} = 190$ and $\alpha_{NR} = 166$, a repulsif effect much stronger (15%) than in the scalar coupling. Corresponding wavefunctions are shown in figure 20. One can see that $f_2 \approx f_1$ at $k \sim 0.3$ and dominates above $k=1$. It is worth noticing the dramatic influence of the form factor in all these calculations: one has for instance $\alpha_{LFD}=103$ for $\Lambda = 5$ and $\alpha_{LFD}=1725$ for $\Lambda=0.3$!

The coupling between the two components f_i is also very important. By switching off the non diagonal kernels $B_{12} = B_{21} = 0$ the coupling constant moves from $\alpha_{LFD} = 190$ to $\alpha_{LFD} = 251$. It has thus an attractive effect which tends to minimize the difference between LFD and NR results.

Quite surprisingly, in the strong binding limit ($B=0.5$) we have found $\alpha_{LFD}=1462$ and $\alpha_{NR}=3065$. Relativistic effects become now strongly attractive ($\alpha_{LFD} < \alpha_{NR}$). An essential

part of this attraction is due to coupling $f_1 - f_2$ of the two components in the LFD wavefunction. By performing one channel calculations one has indeed $\alpha_{LFD}=3001$, what represents a strong reduction in the effect though it remains slightly attractive. We have checked if this happens for different values of the exchange mass μ . For the same binding energy $B = 0.5$ and $\mu = 0.5$ one has $\alpha_{LFD}=1728$ and $\alpha_{NR}=1400$, repulsive once again. This told us the difficulty of talking about relativistic effects in general. They turn to depend not only on the kind of coupling but also on the binding energy of the system and, furthermore, on the mass of the exchanged particle.

The preceding results show a qualitative difference between S and PS cases. Pseudoscalar coupling is by construction relativistic: small and large spinor components are mixed to the first order. Moreover the coupling between f_1 and f_2 is essential even for very weakly bound systems. It is so interesting to study in this case the zero energy limit of the LFD and compare with the non relativistic results. We understand by that the static potential, with the same form factor, including delta function term. The results, displayed in figure 21, correspond to $\mu = 0.5$ and two different cutoff parameters Λ in the form factors. They show the same behavior that was found in the scalar case, i.e. that relativistic and non relativistic approaches did not coincide even for systems with zero binding energies as far as they interact with massive exchanges.

Figure 21: Zero binding limit in LFD (solid) and Schrodinger (dashed) equations with PS coupling and different form factors ($\mu = 0.5$)

5 Summary

We have presented the main ideas of the Light-Front Dynamics formalism in its explicitly covariant version. When applied to nucleon-nucleon system with perturbative wavefunctions, they led to results which are in good agreement with the TJNAF data, even for momentum transfers larger than the constituent masses. Recently, an interesting application of the Light-Front nucleon-nucleon wavefunctions was done to successfully describe the two-body correlations in

light nuclei [8]. These facts indicate the ability of this approach in describing composite relativistic systems and claim for further developments on this theory.

This work was pursued by calculating the Light-Front solutions in the ladder approximation for two-scalar and two-fermion systems and the main results obtained up to now have been summarized in this contribution. Among them we would like to stress the points that follow.

In the scalar case, we have found that the inclusion of relativity has a dramatic repulsive effect on binding energies even for systems with very small $\frac{\langle k \rangle}{m}$ values. The effect is specially relevant when using a scalar model for deuteron: its binding energy is shifted from 2.23 MeV down to 0.96 MeV. This can be corrected by a 10% decrease of the repulsive coupling constant, what indicates the difficulty to determine beyond this accuracy the value of strong coupling constants within a non relativistic framework.

Light-Front wavefunctions strongly differ from their non relativistic counterparts if they are calculated using the same coupling constant. Once the interaction parameters are readjusted to get the same binding energy, both solutions become closer in the small momentum region but their deviations are sizeable at $k \sim m$.

The relativistic effects are shown to be induced mainly by the additional terms appearing in the interaction kernel. Kinematical corrections have only a small influence on the binding energy.

The Light-Front results are found to be quite close to those provided by Bethe-Salpeter equation, for a wide range of coupling constant, despite the different physical input in their ladder kernel.

Even in the zero binding limit, Light-Front and Schrodinger solutions differ ($\mu \neq 0$) both for scalars and fermions. This leads to the conclusion that such systems cannot be properly described by using a non relativistic dynamics.

For the Yukawa model, we found a critical coupling constant below which the $J=0^+$ solutions are stable without any regularization. For the pseudoscalar coupling, these solutions are also stable for all values of the coupling constant but lead to a quasidegenerate $\alpha(B)$ relation. The $J=1^+$ states are on the contrary unstable for both couplings.

Pseudoscalar coupling shows large deviations with respect to non relativistic solution. Wavefunction is dominated by relativistic components at $k \ll m$, even for weakly bound systems. However form factors play there a determinant role.

The question about relativistic effects has no simple answer. The consequences of implementing the Lorentz invariance in a quantum mechanical description of a system are different, following: the nature of its constituents, the kind of interaction, the quantum numbers of the state, its binding energy, and even the mass of the exchanged particle! There are no simple recipes to perform *a priori* evaluations.
